

Aggressive substitutions: focal incentives and population effects

Same selected routing parameters; inventories, navigation and ecological paths may change · all 14 evaluation cells

* Shaded reference row. Points are four-seed means; whiskers are observed minimum-maximum paired differences, not confidence intervals.

Utility = (cumulative consumption + weight × terminal inventory) / horizon. Weighted endpoint wealth remains separate from consumption gains.

These are whole-policy substitutions. Mean off-site shortfall, terminal inventory and every fixed sensitivity remain in the companion tables.

No equilibrium, robust dilemma or institutional conclusion follows from this four-seed comparison. Zero evolutionary runs or experimental model calls.
