

A finite numerical comparison of 18 local foragers

Selected: r4-f50-nearest · one declared sweep · tuning seeds 62001–62002

A Mean consumption and final-quarter consumption

B Retained worst environment and worst cell

* Shaded selected row. Ranking: highest equally weighted mean; then highest final-quarter mean; then smallest candidate ID.

Each candidate: nine rate/need cells × two tuning seeds = 18 environments. Entire sweep: 324 episodes; no adaptive proposals.

Worst-environment and worst-cell values are diagnostics, not selection criteria. All candidates and adverse outcomes are retained.

A supplied-family population baseline; no private optimum, equilibrium, global optimum or independent evolutionary replication is implied.
